NATIONAL PARK SERVICE

RESEARCH/RESOURCES MANAGEMENT REPORT SER-91/01

Watersheds of Great Smoky Mountains National Park: A Geographical Information System Analysis

United States Department of the Interior

National Park Service
Southeast Region

The Research/Resources Management Series of the Natural Science and Research Division, National Park Service, Southeast Regional Office, is the established in-house medium for distributing scientific information to park Superintendents, resource management specialists, and other National Park Service personnel in the parks of the Southeast Region. The papers in the Series also contain information potentially useful to other Park Service areas outside the Southeast Region and may benefit external (non-NPS) researchers working within units of the National Park System. The Series provides for the retention of research information in the biological, physical, and social sciences and makes possible more complete in-house evaluation of internal research, technical, and consultant reports.

The Series includes:

1. Research reports which directly address resource management problems in the parks.

2. Papers which are primarily literature reviews and/or bibliographies of existing information relative to park resources or resource management problems.

3. Presentations of basic resource inventory data.

4. Reports of contracted scientific research studies funded or supported by the National Park Service.

5. Other reports and papers considered compatible to the Series, including results of applicable university or independent research relating to the preservation, protection, and management of resources administered by the National Park Service.

Southeast Regional Research/Resources Management Reports are produced by the Natural Science and Research Division, Southeast Regional Office. Copies may be obtained from:

Parker, Charles R. and David W. Pipes. 1990. Watersheds of Great Smoky Mountains National Park: A Geographical Information System Analysis. U.S. Department of the Interior, National Park Service, Research/Resources Management Report SER-91/01. Southeast Regional Office, Atlanta, Georgia. 126 pp.

ACKNOWLEDGEMENTS

We thank Dr. James R. Carter, Illinois State University, for providing the topographic data, for making us aware of the hypsographic analytic method for elevation, and for discussions of geographic information systems data and analysis in general. Dr. Carter also made insightful comments on an earlier draft of the report.

Several people helped digitize portions of the data; we thank Keith Wilcoxson, Edith Hahn, Sue Powell, and Sean Moran. Hope Barett performed some of the watershed analyses. Keith Langdon, Steve Moore, Jane Farmer, Paul Durr, John Peine, Nicki McFarland, and Jim Renfro reviewed an earlier draft of the report. Jim Wood, NPS SERO, and Gary Larson, NPS CPSU Oregon, made valuable suggestions that improved the quality of the report.

ABSTRACT

This report is the first of several describing the natural resources of the Great Smoky Mountains National Park as incorporated in the park's Natural Resources Database. Streams and watersheds are described and illustrated using a geographic information system (GIS). Streams were digitized from U.S. Geological Survey 7.5 minute topographic quadrangle maps. Watersheds comprising at least 5 km^2 were delimited on the maps and also digitized into the GIS. Data on elevation and aspect were derived from the USGS 1:250000-scale Digital Elevation Model for Knoxville and summarized by watershed. The data were analyzed in terms of stream lengths, watershed areas, drainage densities, predominant aspect, and related statistics. Results are presented in tables, figures, and maps for the entire park, the North Carolina and Tennessee sides, and for the 45 watersheds. Those streams not included in a 5 km^2 watershed are treated in separate pages of tables, figures and maps.

LIST OF TABLES

LIST OF FIGURES

Introduction

This document presents graphic and statistical summaries of the major watersheds of Great Smoky Mountains National Park (GRSM). It is the first of a series of reports summarizing data which have been incorporated into the geographic information system (GIS) of the park. The data in this report represent four of the many themes or data layers in the Natural Resources Database (NRDB) for GRSM. The NRDB is part of a larger effort to acquire and organize data for use by park managers to more efficiently manage the resources under their care, and by scientists to analyze and model the park's ecosystems. This and subsequent reports are designed to serve as references to the major data themes in the NRDB so that potential users will have access to summaries of the information without having to enter the system and learn the specifics of database construction and manipulation. Reports in preparation include forest cover types; disturbance history, including fire history; and geology. Detailed information and analyses are available on request from the GIS Coordinator.

In the past, 28 major watersheds have been recognized (Peine, J.P., C. Pyle, and P.S. White. 1985. Environmental monitoring and baseline data management strategies and the focus of future research in Great Smoky Mountains National Park. SERO R/RM Report SER-76) in GRSM (Fig. 1). These watersheds were defined in such a way that no park land was excluded from a watershed. Hydrologic accuracy was not a primary consideration. However, the Long-Term Ecological Research and Monitoring project and other scientific studies require hydrologically accurate watershed maps for study design and other analyses. For these reasons it became necessary to delimit accurate watersheds and provide descriptions of the basic features of each. In the NRDB, the park's watersheds have their mouth at the point where a stream crosses the park boundary or at the normal pool level of the Tennessee Valley Authority reservoir that a stream flows into. They encompass all lands within an area defined by the ridge lines on the United States Geological Survey's (USGS) 7.5-minute topographic quadrangle maps from

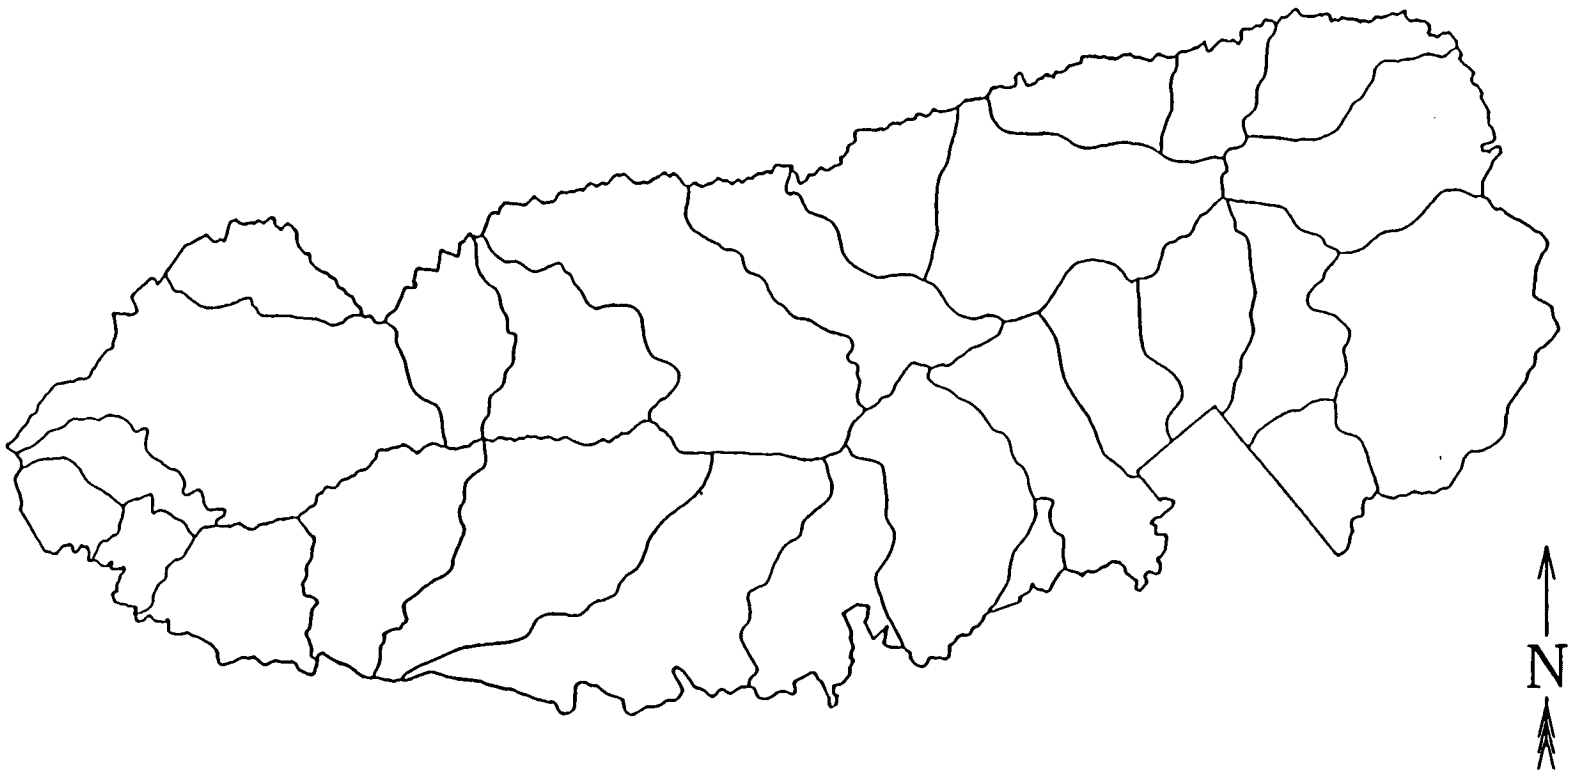

Figure 1. Management watersheds, Great Smoky Mountains National Park.

the mouth back to the same point, with a minimum size limitation of 5 km^2. These guidelines resulted in a new map that recognizes 45 watersheds (Fig. 4). Summary statistics of each watershed are given in Table 1. An exception to the 5 km^2 size requirement is White Oak Sinks (4.3 km^2), which was included because of its unique hydrologic and floristic characteristics.

Some streams near the boundary of the park were excluded from the watersheds (see page 21). The largest areas excluded lie between Cosby and the Middle Prong of the Little Pigeon River on the north side of the park and along Fontana Lake on the south side of the park. In these areas, numerous small creeks cross the park boundary or flow into the lake. The boundary line in certain areas follows the middle of the streams for some distance. In addition, lands outside the park boundary are included in certain watersheds, most significantly Abrams Creek. Since the goal was to represent hydrologically accurate watersheds, this was unavoidable. The Abrams Creek watershed includes the area known as Happy Valley up to the ridge line of Chilhowee Mountain. This incorporates 2256.85 ha of non-park land that comprises 11.5% of the Abrams Creek watershed. Other watersheds include smaller portions of non-park land.

The watersheds of Oconaluftee River (West) and Bradley Fork may be treated as separate watersheds, or they may be combined with the small lower segment of the Oconaluftee and be regarded as a single large watershed, Oconaluftee River. The area called Oconaluftee River (Lower) is not a natural watershed and does not represent an independent unit suitable for study. It is included here to permit the option of either combining these three into a larger single watershed or retaining the two natural units for independent analysis. Both options are used in our analyses of themes in this report and will be used in subsequent reports. Similarly, the East, Middle, and West Prongs of the Little River are natural watersheds which may be combined with the portion called Little River (Lower) to form a single watershed that begins at the park boundary and encompasses all three drainages.

Methods

Hardware and Software

GRSM has a commercial GIS package known as ERDAS, which stands for Earth Resources Data Acquisition System. The system in the Science branch of the combined Resource Management and Science Division is implemented on a Dell System 310 computer with a 386 microprocessor, a 387 mathcoprocessor, and a 150 MByte hard drive. Digitizing is done on a GTCO 2436 L digitizing tablet. A comparable system at park headquarters is installed in the Resources Management branch of the division on a Compaq Deskpro 386 similarly equipped. All data discussed in this report are duplicated on the system at headquarters.

Watershed Digitizing

The watersheds were first delimited on USGS topographic maps and then digitized into separate files. For consistency, each watershed boundary was digitized clockwise. Each digitized file was plotted to scale, overlaid on the appropriate topographic maps and checked for accuracy. All watersheds have common boundaries with other watersheds. Since it was impossible to digitize a line exactly the same twice, each common boundary was digitized only once. A program was written using the ERDAS Toolkit that permitted extraction of the desired segments from a file, reversal of the segments' direction if necessary, and insertion into another file. A second program permitted rearrangement of the pieces into the correct sequence, and a third program permitted assembly of the smaller pieces of boundary into one or two large segments that represent the entire watershed boundary. Each watershed was stored in a separate file. Finally, all watersheds were combined into a single watershed file that can be used for thematic analyses. Appendix A lists the watershed boundary data files.

Stream Digitizing

All streams shown on USGS topographic maps were digitized by stream order. Streams having no tributaries are called first-order streams. When two first-order streams come together they form a second-order

stream; when two second-order streams come together they form a third-order stream; and so on. Tributaries of a lower order do not affect the numbering of a higher order stream; i.e., a first-order stream joining a second-order stream will not change the second-order stream to third-order. To achieve maximum flexibility in working with the streams, every tributary and segment of a stream between consecutive tributaries was digitized separately. The streams were plotted to scale and overlaid on the topographic maps to check for accuracy. Corrections were made whenever necessary. Stream segments were stored separately in the data files, and were entered in the files in a manner that ensured that the coordinates of each segment were arranged from the upstream end to the downstream end of the segment. Finally, the individual segments were collected together into an appropriate watershed file. Thus, for example, all streams of the Big Creek watershed were stored in a single file called BIG.DIG, and all streams of the Noland Creek watershed were stored in a file called NOLAND.DIG. These files are listed and summarized in Appendix A along with the watershed boundary files.

Slope, Elevation, and Aspect

Topographic features were derived from USGS 1:250,000-scale elevation data for the region provided by Dr. James Carter, Department of Geography, University of Tennessee. The elevation data for the park and a portion of the surrounding area were extracted from the much larger USGS data set. Slope and aspect were calculated by Dr. Carter during the extraction process and were provided as separate files along with elevation. A nearest-neighbor analysis was used to subsample the three files and convert the data to ERDAS format GIS files. While working with the elevation and aspect data several systematic errors were discovered. These errors are discussed in Appendix B.

Watershed Statistics

Each page of watershed statistics was arranged as follows. The perimeter is given in feet, miles, meters, and kilometers, and is a direct measurement of the length of the watershed boundary. The slope-

corrected **area** is given in square feet, square miles, acres, square meters, square kilometers, and hectares. **Shape** is a unitless measure that compares the area of the watershed with the area of a circle having the same circumference as the perimeter of the watershed. If the watershed is a perfect circle, then its **shape** would equal 1.0. The larger the difference of **shape** from 1.0, the less circular the watershed. This statistic, also known as shoreline development, is used by limnologists to describe lake morphology. **Elevation** is measured at the lowest point in the watershed, where the stream leaves the park or enters a reservoir, and at the highest peak in the watershed. The measurements were read from topographic maps and are given to the nearest contour interval (nearest 40 feet in most cases) unless a benchmark was available. Normally, the lowest elevations are accurate to the nearest contour interval, whereas the highest elevations are accurate to the nearest foot because the elevation of peaks is usually recorded on topographic maps. **Elevation** is given in both feet and meters. The **Total Length of Streams** was determined from the digitized stream files, and is given in feet, miles, meters, and kilometers. The **Drainage Density** is a measure of the length of streams in the watershed as a function of the area of the watershed. Units are given in either miles stream/mile^2 watershed or km stream/km^2 watershed. The table that follows **Drainage Density** lists the number and total lengths of stream segments by stream order. (The number of segments is equal to the total number of streams only for first-order streams.) Length is given in meters only. For Abrams Creek, Deep Creek, Oconaluftee River (Lower) and Cataloochee Creek, a final measure given was the number and area, in hectares, of **ponds** in the watersheds. These are ponds that are indicated on topographic maps. They are not visible on the watershed maps presented here because they are too small.

The two graphs at the bottom of each watershed statistics page depict the prevailing aspect and the distribution of elevation in the watershed. The aspect is shown as a polar coordinates plot (rosette), in which the number of pixels having a particular orientation is placed an appropriate distance from the center of the circle at an angle that

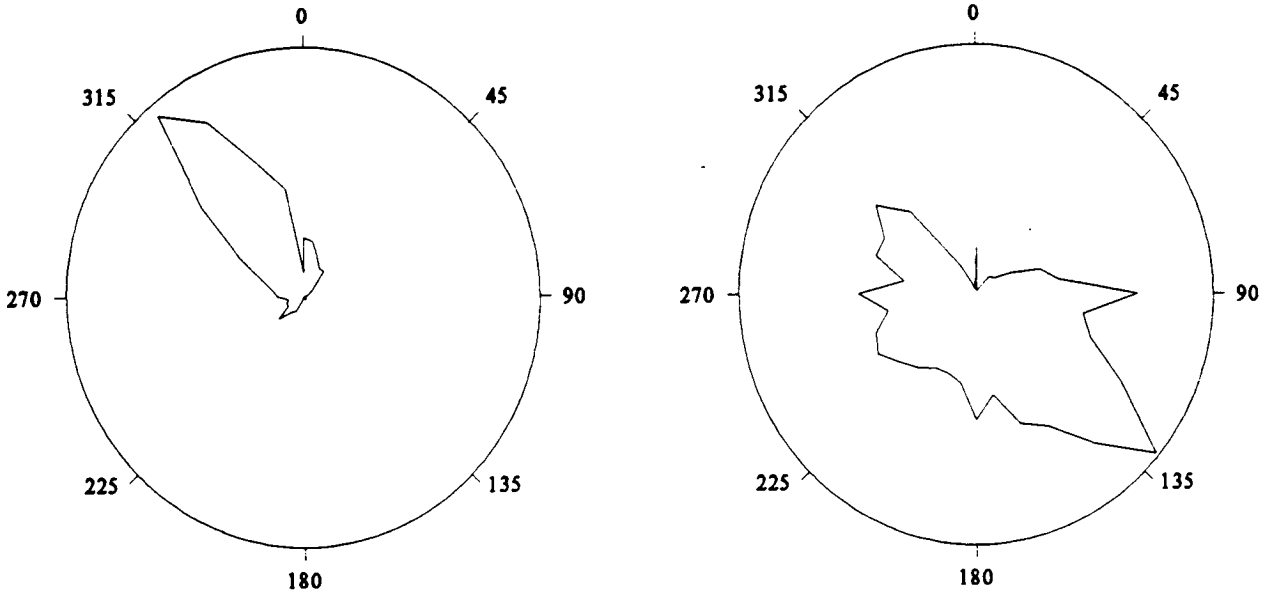

Figure 2. Polar coordinates plots of aspect in Indian Camp Creek (left) and Noland Creek (right) watersheds. Aspect is in 10° increments. Both plots are scaled to have the same radius.

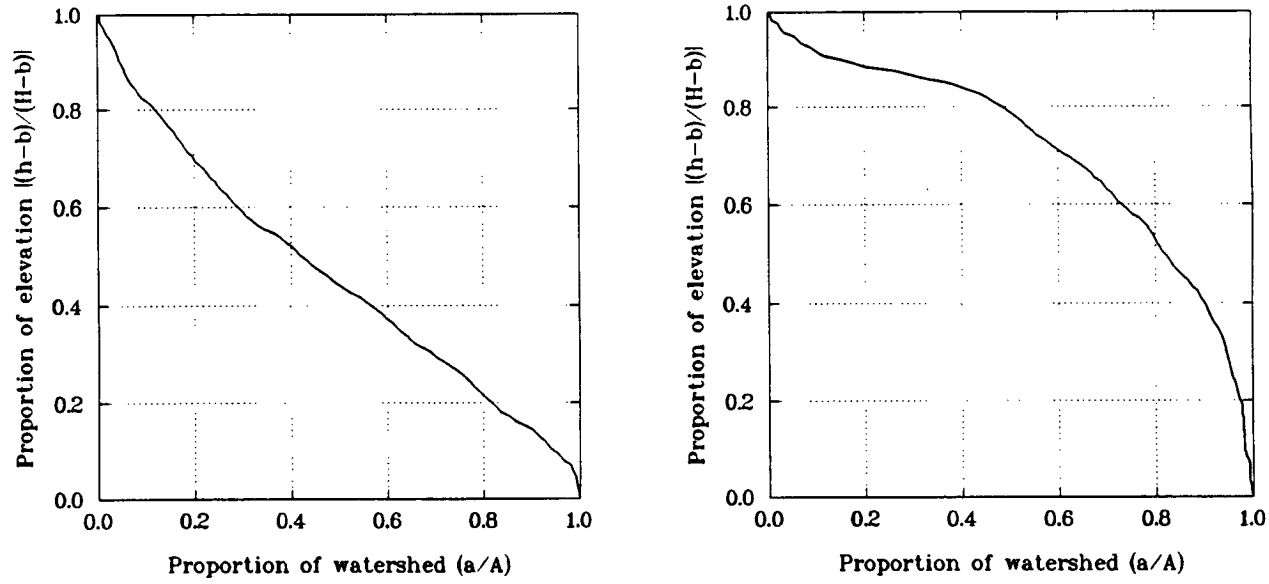

Figure 3. Hypsometric curves of elevation in Middle Prong Little River (left) and West Prong Little River (right). The x-axis of each graph is the proportion of the area of the watershed above or below a given elevation, which is expressed on the y-axis as a proportion of the total range in elevation in the watershed.

corresponds to its aspect. Figure 2 shows rosettes of aspect for watersheds of contrasting orientation. Indian Camp Creek is located in the northeast quadrant of the park and has a predominant northwest orientation. Noland Creek is located on the south side of the park and has a predominant southeast orientation. In comparing the aspect rosettes of different watersheds, the lengths of the spikes are unimportant. The only meaningful comparison is the prevailing direction.

The graph on the right side of each page is a hypsometric curve of the elevation of the watershed. In these graphs, the distribution of elevation in the watershed is depicted as a cumulative curve showing the percentage of the watershed above (or below) a given elevation. The graphs for different watersheds are directly comparable because both axes are standardized. For example, in Fig. 3 the hypsometric curves of Middle Prong Little River and West Prong Little River are plotted side-by-side at identical scales. This was accomplished by converting all elevations into altitudes above the watershed minimums and expressing these as a proportion of the highest elevation above the minimum. The x-axis represents the area of the watershed above a given elevation as a proportion of the total area of the watershed. In contrasting the Middle and West prongs of the Little River, we see from the figure that there is no prevailing elevation in the Middle Prong but that it increases steadily in altitude from the lower to the upper elevations. The West Prong, on the other hand, gains elevation rapidly from the lower end (1.0 on the x-axis) so that over 80% of the watershed (0.8 on the x-axis) is at an elevation above the mid-elevation (0.5 on the y-axis) of the watershed. This manner of depicting the distribution of elevation in watersheds is taken from R. Hammond and P. McCullagh, Quantitative Techniques in Geography: An Introduction, Clarendon Press, Oxford, 1974.

Opposite each watershed statistics page is a map of the watershed and the streams. Each watershed is depicted with north at the top of the page. Scales are not given for the separate watershed maps, but may be inferred from the whole park map on page 13.

The aspect rosettes, elevation hypsographs, and watershed maps were created using SYSTAT/SYGRAPH, a commercial statistics and graphics software package. For the aspect and elevation graphics, data were extracted from the ERDAS GIS files and written to ASCII files accessible by SYSTAT, converted into SYSTAT format and plotted using SYGRAPH. The watershed maps similarly were written in a format acceptable to SYSTAT and converted into SYGRAPH map files. The graphs and the watershed maps were converted to computer graphics metafile (CGM) format. The CGM files were read by WordPerfect 5.1. Sizing and page placement were accomplished within WordPerfect.

System Accuracy

Several sources of error place limitations on the reliability of the data presented in this report. The data were digitized from 1:24,000-scale maps. In this process, a map was taped to the digitizing tablet and the features were traced with a cursor, while a button on the cursor was periodically pressed to send coordinates to the computer. For proofing, the data were plotted on a sheet of paper and then placed over the original map for examination on a light table. Errors were corrected either by redigitizing portions of the map or by editing the data file directly. Sources of error in this process included:

1. Registering the map with the digitizing tablet. The digitizing tablet has a resolution of 0.025 mm, or over 1000 lines per inch. This far exceeds the ability of the operator to align the digitizing cursor. Therefore, when setting up each map for digitizing, we accepted a setup that came within 50 meters of the test coordinates. This represented an accuracy of better than 0.5%.

2. Tracing with the cursor. This step requires patience and attention to detail. Not only must the crosshairs of the cursor align properly with the feature being digitized, but the decision of when to press the button to send coordinates to the

computer also affected accuracy. The more curved a line, the more frequently the cursor button must be pressed to record the curves. Thus, the digitizing accuracy was highly operator-dependent. For the most part, however, errors made at this point were caught and corrected in the proofing stage.

3. In plotting a digitized file to check for accuracy, coordinates from the original topographic map must be transferred to the plotter paper, and then these points must be registered with the plotter. Both of these steps are "eyeball" operations with attendant errors. Our estimated accuracy for this step was ±1 mm for each of the 3 registration points.

4. When overlaying the plotted maps on the originals, we checked for errors of omission, excess and incompleteness, as well as registration. The first three types of errors were relatively easy to detect and correct. Missing stream segments were simply digitized and added to the file. Overshoots, in which lines cross rather than meet exactly, and undershoots, in which lines fail to meet, were corrected by editing the file. Registration errors, however, were more difficult or impossible to correct. The digitized path of a stream might follow the mapped stream path closely at first, but become more and more displaced from the mapped path as the stream progressed from one side of the map to the other. Unless displacement was greater than 1.5 mm, we did not correct for it.

5. Errors in the topographic maps. While digitizing the streams, several inconsistencies were discovered. For example, the Mt. LeConte Quadrangle shows a tributary joining Rocky Spur Branch at approximately 2760 ft elevation, immediately after passing under the Roaring Fork Motor Nature Trail. However, Rocky Spur Branch passes under the road and joins the unnamed tributary on the east side of the road. Rocky Spur Branch then flows into Roaring Fork at 2560 ft elevation. Other mapped

streams inconsistent with our knowledge of the field include LeConte Creek and Scratch Britches Creek, and Eagle Rocks Prong and Chapman Prong. A more common error is exemplified by Marks Creek. Marks Creek is shown in the lower left corner of the Gatlinburg Quadrangle at approximately 3560 ft elevation, just below Bearpen Gap. The stream flows southwest to the edge of the map, but is not shown as a stream that continues onto the adjacent Wear Cove Quadrangle. After several trips to the site and after examining aerial photographs of the area, we were able to redraw the Marks Creek area in a manner that more accurately depicts reality than that shown on the topographic maps. The plot of streams shown in the figure of Middle Prong Little River includes the corrected Marks Creek area. This type of problem occurred in several other areas as well, but normally involved a small portion of stream. Most of these discrepancies were corrected without field reconnaissance.

Of these sources of error, the last one -- errors in the topographic maps themselves -- seems the most egregious. Not all of the known discrepancies have been corrected; some of the corrections themselves may be in error; and undoubtedly other errors have not been recognized. Until updated and more accurate topographic maps become available from USGS, we feel that our digitized data of the streams in the park can be considered to be at least as reliable as the original topographic maps, and the measurements made from them represent the best available estimate of the watershed and stream characters for GRSM.

Table 1. Watershed summary statistics.

	Watershed	Area (km^2)	Shape	Elevation Low - High (meters)	Drainage Density (km/km^2)
1	Cosby Creek	27.80	1.68	500 - 1804	2.34

Appendix A
Data Files

All of the data files created for this project are in ERDAS DIG format. These are fixed format ACSII files that can be accessed in sequential or random mode. The structure of these file is explained in detail in the ERDAS User's Guide, Appendix B. For each watershed there are two files, one containing the stream coordinates and one containing the watershed boundary coordinates. In addition there is one file for the streams not contained in a named watershed, and one file of the boundary of GRSM. These files are listed in Table A1. Because both stream files and watershed boundary files have the same name, it is necessary to keep the files in different subdirectories or on separate floppy disks. On the GIS computers at Uplands and at Headquarters they are kept in separate sub-directories named \STREAMS and \WTRSHDBN, respectively. Backup copies are on separate, labeled diskettes. Backup copies are kept at Uplands and Headquarters.

Streams are recorded in the files by stream segment. Stream order is stored as the GIS value of the segment minus 1. For example, a stream having a GIS value of 2 has an order of 1, and a stream segment of GIS value 3 has an order of 2. In the boundary files, only a single item is stored, with the exception of East Prong Little River which has two items. This is because of an undocumented limitation in ERDAS that prevents individual items from exceeding 5000 points, and the boundary of the East Prong Little River exceeded that number. The GIS value of boundary items is the same as the watershed numbers used in the report. Little River (Combined) has a GIS value of 46, and Oconaluftee River (Combined) has a GIS value of 47.

Table A1. Stream and boundary data files. Files are in ERDAS DIG format.

Appendix B
Topographic Data

The topographic data used in this report were derived from the USGS Knoxville W 1/2 1:250,000-scale Digital Elevation Model (DEM), the only complete elevation data set for the entire park. The data were obtained by Dr. James Carter of the University of Tennessee. DEM data are arrayed on a grid in which each data point represents an elevation in meters for the geographic location represented by the point. Slope and aspect data were calculated from the elevation data for each point by a spatial derivative algorithm written by Dr. Carter (Carter, J. 1990. Some effects of spatial resolution in the calculation of slope using the spatial derivative. Technical Papers, 1990 ACSM-ASPRS Annual Convention, Volume 1:43-52.).

In the 1:250,000 DEM the points are 3 seconds apart east to west and north to south. This represents a spacing of approximately 90 m by 75 m. However, since the data are arrayed in latitude and longitude, there is greater separation between the points in the south than between those in the north. These considerations make the translation of data from the DEM to the constant square 90 m by 90 m pixels of the GIS complicated. A program was written that used a nearest-neighbor approach to select the most appropriate value for each pixel. After selecting the appropriate data point, the corresponding elevation, slope, and aspect data were written into separate ERDAS GIS files. Then separate analyses by watershed were conducted to obtain the watershed statistics used in the aspect rosettes and elevation hypsographs.

During construction of the aspect rosettes, large spikes were noted along the cardinal axes (Fig. B1). Carter determined that the spikes were the result of the use of integer elevation values, and the effects were greatest at gentle slopes (<10°), but even at 45° slope only 26

distinct categories of aspect can be computed (Carter, J. submitted. The effect of data precision on the calculation of aspect using gridded DEMs. Photogrammetric Engineering and Remote Sensing.). These same considerations apply to the calculation of slopes from integer elevation data in DEMs, but slope calculations are not affected to the same degree as aspect calculations. Since DEMs are available only in integer format there is no way to obtain more precise aspect data. Therefore, we have combined the aspects calculated at 1° increments

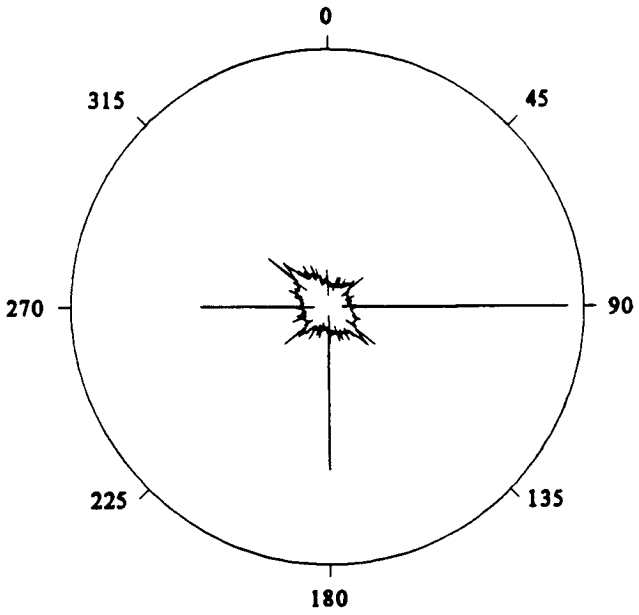

Figure B1. Aspect rosette of park in 1° increments of aspect.

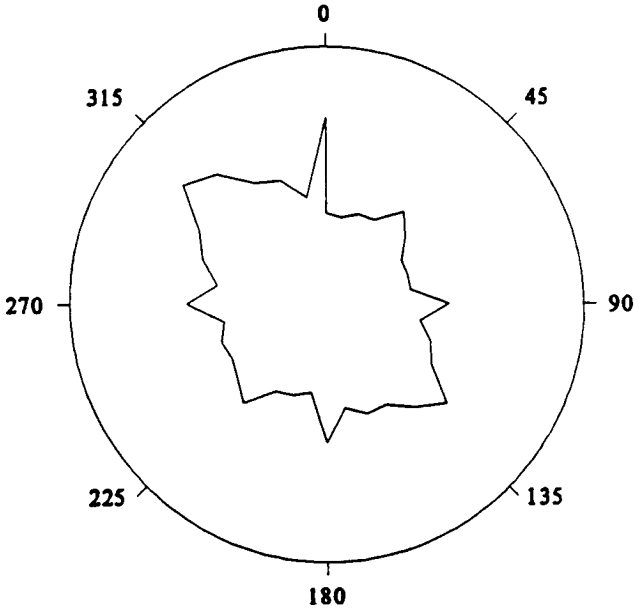

Figure B2. Aspect rosette of park in 10° increments of aspect.

into 10° increments. This smoothes the data and has the effect of reducing the spikes shown in Fig. B1 into the more interpretable form shown in Fig. B2. Spikes still are evident at the cardinal compass points, but are much reduced.

Additional problems with the DEM data were discovered while performing other operations on the data. Fig. B3 is a plot of the differences between elevations in the DEM and 776 digitized elevations from the 7.5 min quadrangles. The elevations were digitized from benchmarks and

other clearly labeled elevation points on the maps. These data were gridded into an ERDAS GIS file and overlain with the DEM data in the elevation GIS file for comparison. It is clear from the figure that there is a large systematic underestimate of elevations in the DEM. While there is no reason to expect exact correspondence between the two data sets, the degree of disparity is great. Differences between the two ranged from -117 m (DEM greater than digitized elevation) to +171 m (digitized elevation greater than DEM), and averaged 30.9 m ($P<.0001$,

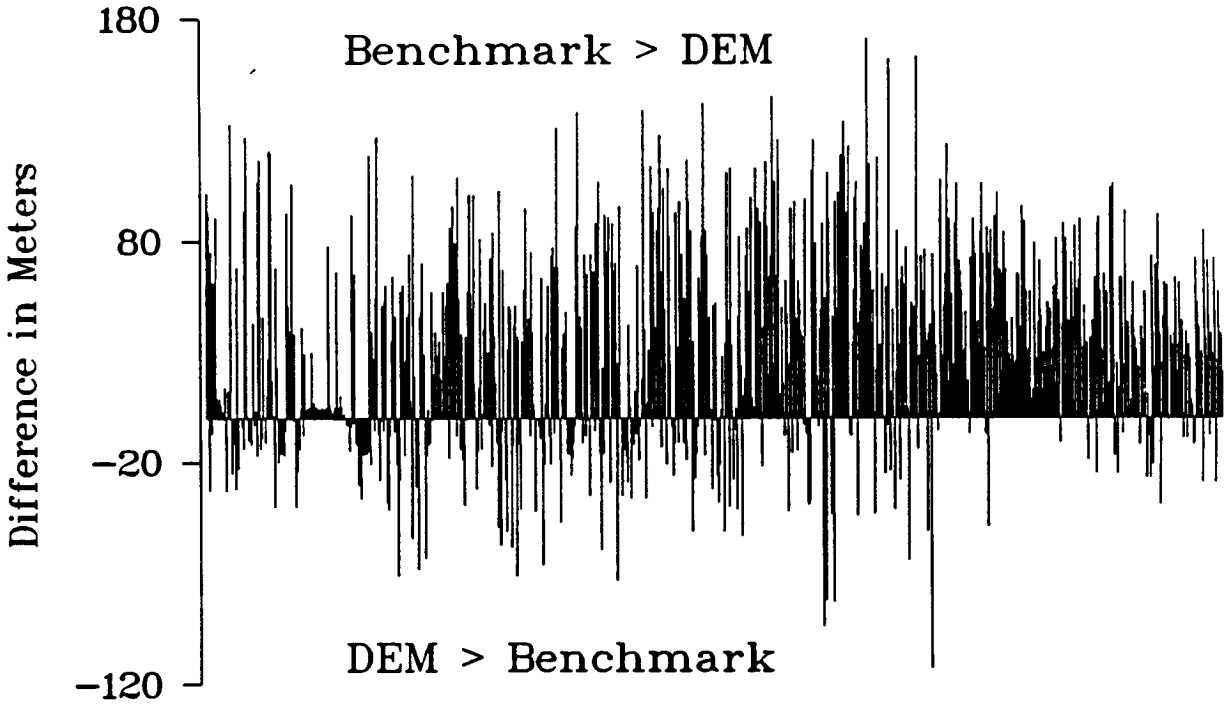

Figure B3. Differences between elevations digitized from 7.5 min topographic quadrangles and those from the Knoxville W 1/2 1:250000-scale DEM for Great Smoky Mountains National Park. Elevations are sorted in increasing order from left to right.

paired sample t-test). The average absolute difference between elevations was 43.0 m. Since the digitized elevations frequently represent mountain peaks and other prominent features of the landscape, it may not be surprising that the DEM elevations are lower than the digitized elevations. However, the degree to which the DEM

underestimates the elevation seems too great to be simply a matter of high elevation bias in the digitized data set.

Fig. B4 illustrates a second type of error found in the DEM. This is a plot of the frequency at which each elevation occurs in the DEM, or in the portion of it available to the authors. The large, uniformly

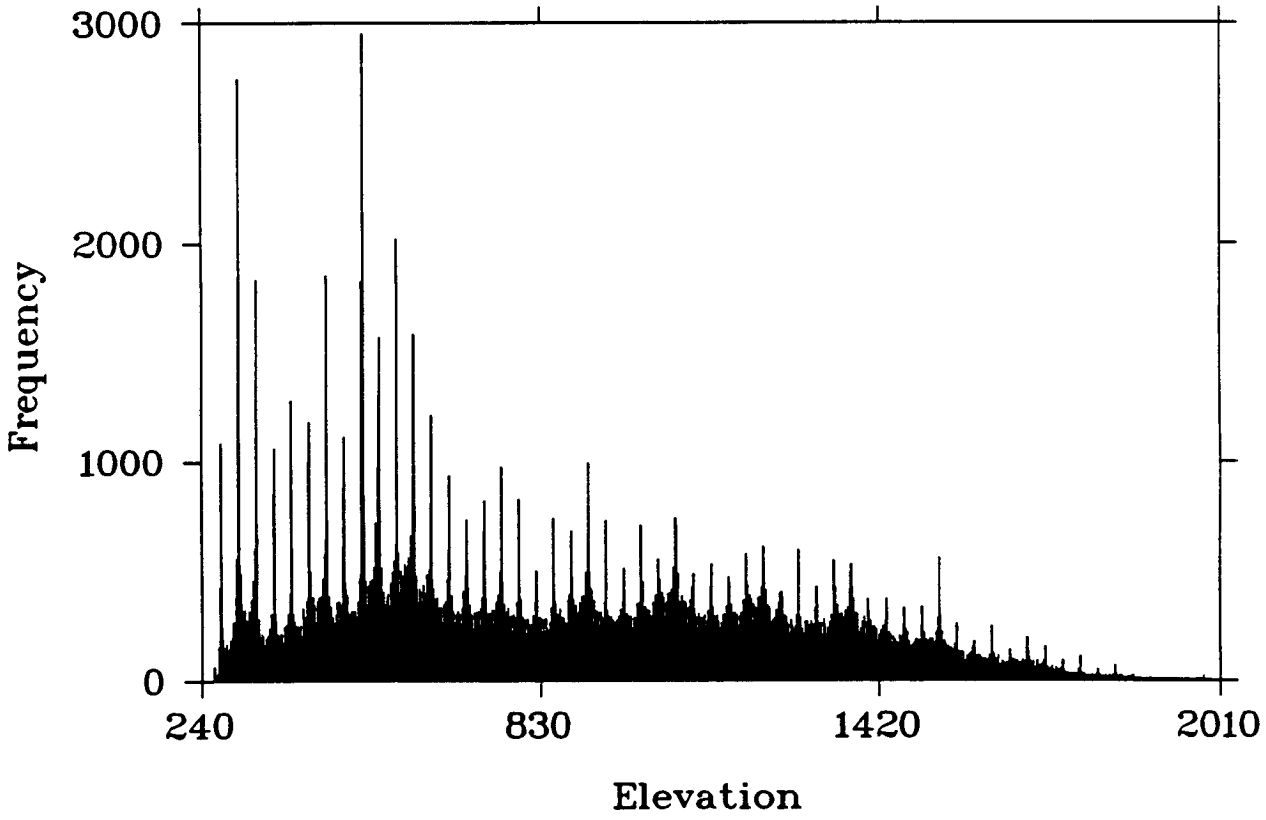

Figure B4. Frequency of elevations in the USGS Knoxville W 1/2 1:25000-scale DEM for 420645 points in and around Great Smoky Mountains National Park.

spaced spikes throughout the plot represent unusually high frequencies of elevations that are at intervals of approximately 31 m. A listing of a portion of the data is presented in Table B1. Dr. Carter believes this spacing represents the original 100 ft interval of contour lines on the 1:250000-scale maps from which the DEM was created. He suggests that this type of anomaly could result if an algorithm was used while

digitizing that interpolated the elevation of a point between two contour lines as being the same as one of the contour lines if the point was within a certain distance of the line. This would lead to a considerable overestimate of elevations equal to those of the contour intervals, accounting for the uniform spacing seen in Fig. B4. The actual algorithm used in digitizing apparently has not been published (A.A. Elassal and V.M. Caruso. 1983. USGS digital cartographic data standards. Digital elevation models. U.S. Geological Survey Circular 895-B. 40pp). Note that the highest spike in Fig. B4 corresponds to an elevation of 521 m in Table B1. This spike represents the normal pool elevation of Lake Fontana and is in fact a normal feature of the landscape, not an aberration.

Finally, when the elevation file derived from the DEM data is displayed on a graphics terminal in black and white, uniformly spaced diagonal lines are visible. These lines are oriented from the southwest to the northeast, and are approximately 4837 m apart (distance along the ground). The lines appear in files derived from the elevation data, and are quite intrusive once they have been noticed. As of yet no explanation has been advanced to explain the origin of these lines, but they clearly do not represent natural features of the landscape. Other types of non-random lines have been found by researchers using different DEM data sets (J.R. Carter, pers. comm.).

Table B1. Partial listing of elevation frequencies from USGS Knoxville W 1/2 1:250000-scale DEM. Elevations corresponding to approximate 100 foot contour intervals are highlighted.

As the Nation's principal conservation agency, the Department of the Interior has responsibility for most of our nationally owned public lands and natural resources. This includes fostering the wisest use of our land and water resources, protecting our fish and wildlife, preserving the environment and cultural value of our national parks and historical places, and providing for the enjoyment of life through outdoor recreation. The Department assesses our energy and mineral resources and works to assure that their development is in the best interests of all our people. The Department also has a major responsibility for American Indian reservation communities and for people who live in island territories under U.S. administration.
